Abstract— Convolutional Neural Network (CNN) becomes the most powerful tool for object detection application and is mostly used in several filed such as security and medical. Bone fracture detection is one of the most medical application which will be useful in the medical treatment since there are number of misdetections according to human errors and small fracture locations. YOLO is the advanced CNN model that is interesting for researchers to be implemented with several applications. The YOLO-X and YOLO-R are the current models which are implemented in many applications. However, these models have not been evaluated on the low feature images such as bone X-ray images. Therefore, in this paper, we comprehensively study the performance of YOLO-X and YOLO-R under fracture bone X-ray images to locate the fracture locations. As a result, YOLO-X presents faster convergence time with much higher accuracy than YOLO-R since the YOLO-X model locates the fracture area with alternative processing such as detection head decoupling, anchors-free and augmentation strategies. Then, it can detect the fracture locations even if the features of X-ray images are low.

Keywords— Machine learning, CNN, YOLO, bone fracture.

I. INTRODUCTION

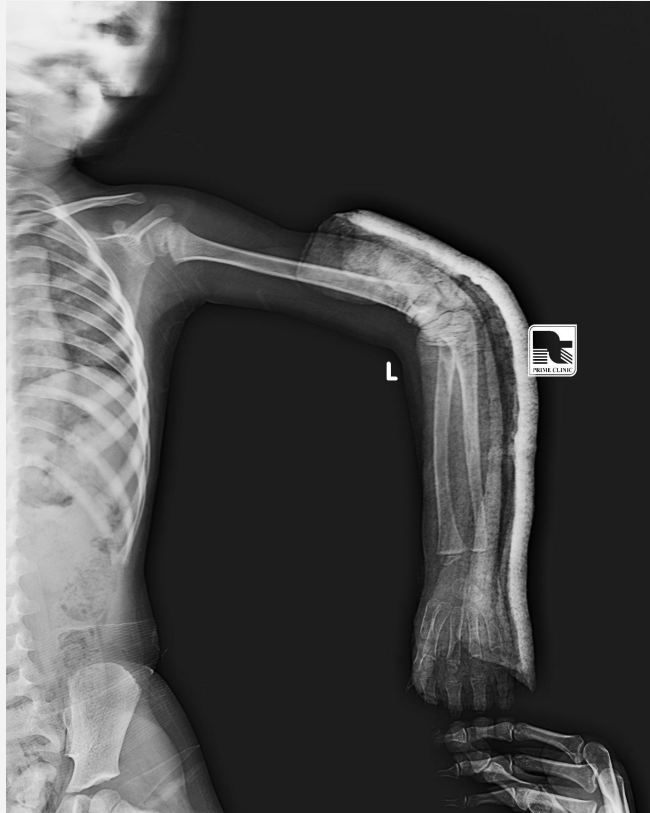

application with machine learning is exploited, not only the misdiagnosis can be reduced, the diagnosis time also significantly reduces. Once the X-ray image is considered as a grayscale image with low features, it is very difficult to classify the fracture area with a conventional CNNs.

A few early studies have shown the feasibility of CNNs usage to detect fractures on radiographic images. In [5], Y. L. Thian and team presented an automated fracture detection and localization on wrist radiographs using model Inception-ResNet Faster R-CNN which were able to attain the area under the receiver operating characteristic curve (AUC) of 0.91. Rebecca and Anuj [1] presented an assessment of a deep-learning system for fracture detection in musculoskeletal radiographs which were able to attain an area under the receiver operating characteristic curve (AUC) of 0.974.

Yolo models [6] are the most popular machine learning model exploiting the CNNs to detect objects such as car, licensed plate, human, face and so on. Different series of Yolo model are presented with alternative solutions to improve the performance of the traditional CNN. Lately, YOLO-R [7] and YOLO-X [8] are the two most interesting techniques among other series to perform the object
